# Introduction to Graphs

## Definition

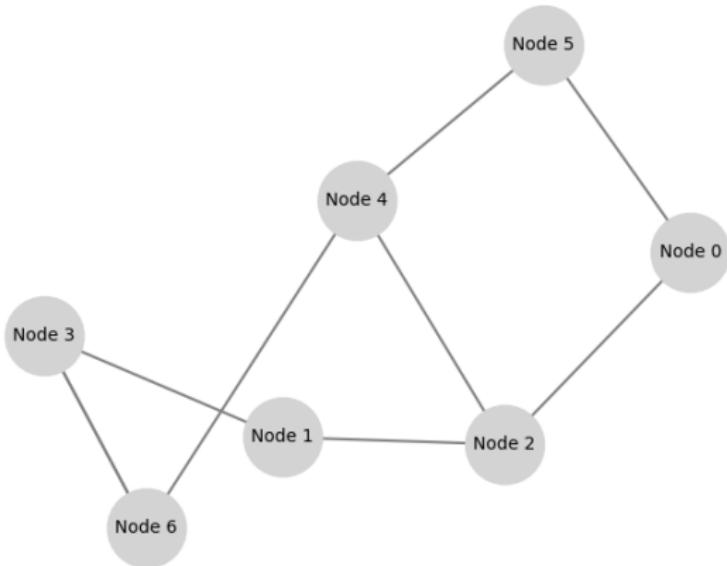

A graph is defined as:

$$G = (V, E, u)$$

- ▶ **Nodes (Vertices):** The set  $V$  represents the nodes in the graph.
- ▶ **Edges:** The set  $E \subseteq V \times V$  represents the connections (relationships) between the nodes.
- ▶ **Features:** Each node can have a feature vector  $u(v)$  representing its attributes.
- ▶ **Labels:** Nodes (or edges) can also have labels, which are used for tasks like classification.

# Example Graph

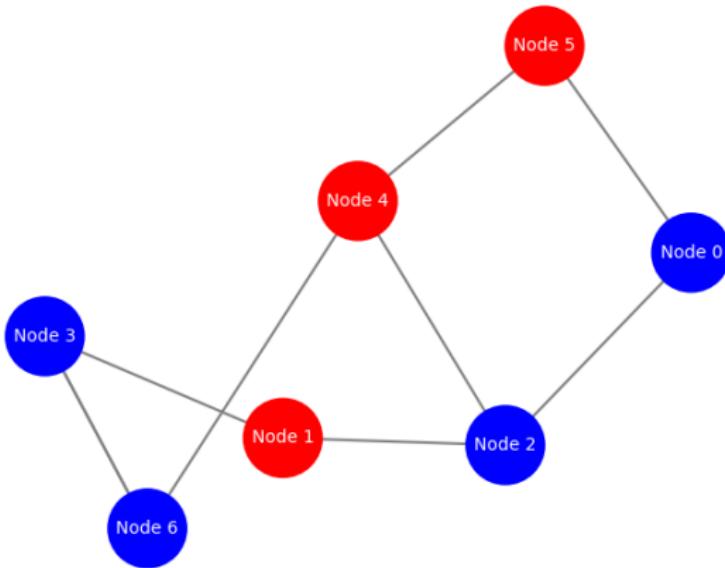

**Example:** The graph below has 7 connected nodes ( $V = \{0, 1, 2, 3, 4, 5, 6\}$ ) and their edges ( $E$ ).

# Example Graph: Node Labels

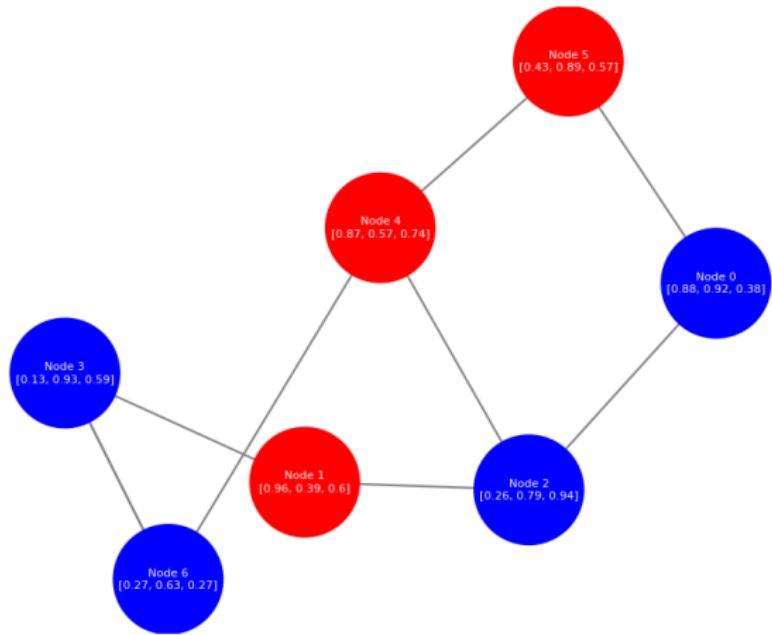

**Example:** Nodes in a graph can be associated with labels.

**Blue nodes:** Label 0    **Red nodes:** Label 1

# Example Graph: Node Features

**Example:** Each node in the graph can have associated features. In this case: Each node has a feature vector of dimension 3.

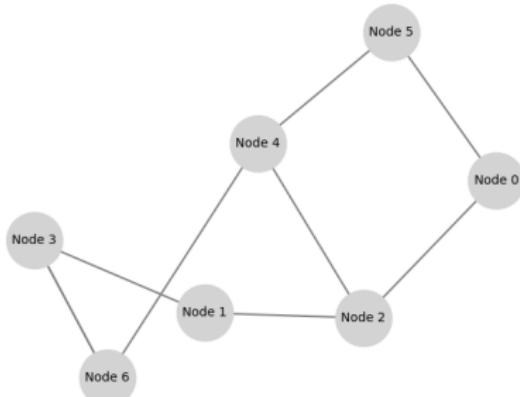

# Adjacency Matrix

## Definition

The adjacency matrix  $A$  of a graph  $G = (V, E)$  is a matrix of size  $|V| \times |V|$ , where:

- ▶  $A[i][j] = 1$  if there is an edge between node  $i$  and node  $j$ .
- ▶  $A[i][j] = 0$  if there is no edge between node  $i$  and node  $j$ .

**Example:** A graph and its corresponding adjacency matrix:

**Adjacency Matrix:**

$$A = \begin{bmatrix} 0 & 0 & 1 & 0 & 0 & 1 & 0 \\ 0 & 0 & 1 & 1 & 0 & 0 & 0 \\ 1 & 1 & 0 & 0 & 1 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 & 0 & 1 & 1 \\ 1 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 1 & 0 & 0 \end{bmatrix}$$

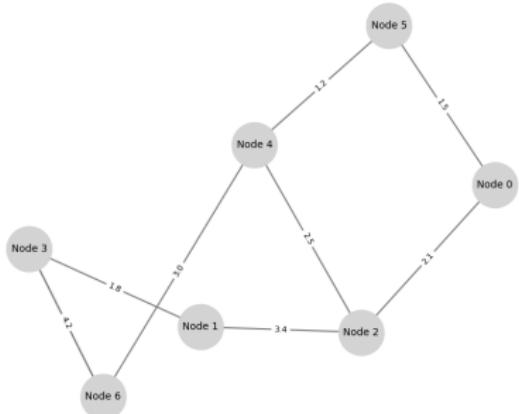

# Weighted Adjacency Matrix

## Definition

The adjacency matrix  $A$  can be extended to a weighted matrix  $W$ , where:

- ▶  $W[i][j]$  represents the weight of the edge between node  $i$  and node  $j$ .

**Example:** A graph and its a weighted adjacency matrix:

**Weighted Matrix:**

$$W = \begin{bmatrix} 0 & 0 & 2.1 & 0 & 0 & 1.5 & 0 \\ 0 & 0 & 3.4 & 1.8 & 0 & 0 & 0 \\ 2.1 & 3.4 & 0 & 0 & 2.5 & 0 & 0 \\ 0 & 1.8 & 0 & 0 & 0 & 0 & 4.2 \\ 0 & 0 & 2.5 & 0 & 0 & 1.2 & 3.0 \\ 1.5 & 0 & 0 & 0 & 1.2 & 0 & 0 \\ 0 & 0 & 0 & 4.2 & 3.0 & 0 & 0 \end{bmatrix}$$

# Applications of Machine Learning on Graphs

**Applications:** Machine Learning on graphs enables a variety of tasks, including:

- ▶ **Node Prediction:** Predict properties or labels of nodes in a graph (e.g., user classification in social networks).
- ▶ **Link Prediction:** Predict the existence or strength of a connection between two nodes (e.g., recommendation systems).
- ▶ **Graph Classification:** Assign labels to entire graphs (e.g., chemical compound classification).
- ▶ **Clustering:** Group nodes into communities or clusters based on their properties or structure.

# Objective: Node Classification

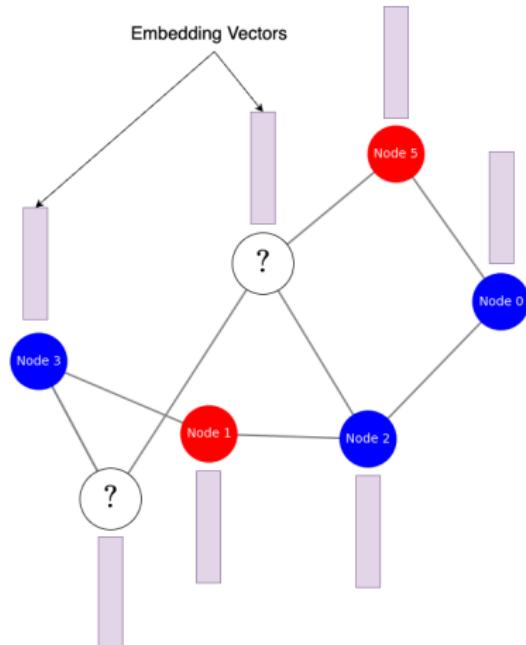

**Objective:** The objective of this course is two-fold:

- 1. Learning a  $D$ -dimensional representation:**

Create embedding vectors for nodes that capture the structure of the graph.

- 2. Node Classification:**

Use the learned embeddings to predict the labels of the nodes.

# Outline

Graph Terminology and Representation

Graph Representation Learning: DeepWalk and Node2Vec

Graph Neural Networks

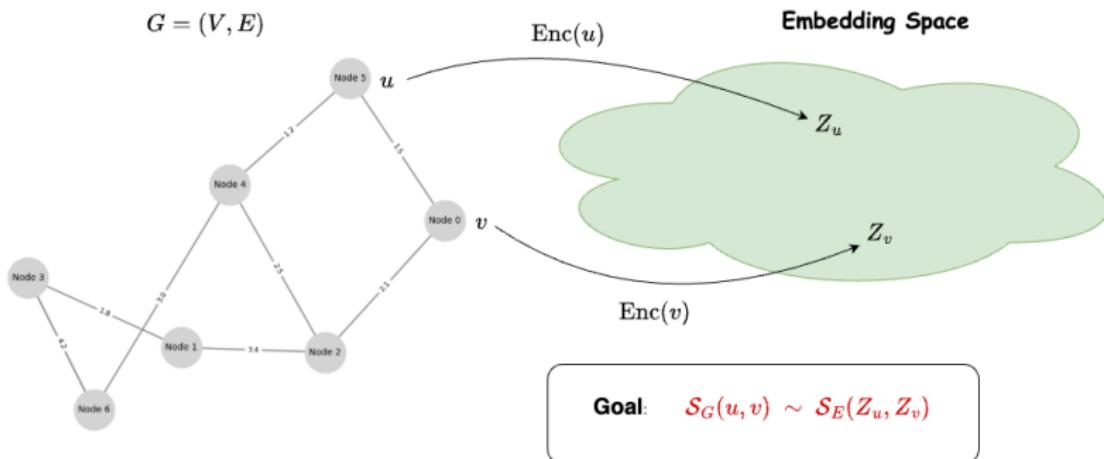

**Objective:** We aim to learn a mapping:

$$f : V \rightarrow \mathbb{R}^D$$

where each node  $u \in V$  is mapped to a  $D$ -dimensional vector  $\mathbf{z}_u \in \mathbb{R}^D$ .

- ▶ In this section, we focus on leveraging the graph's **structure** to generate embedding vectors for nodes.
- ▶ The embeddings can be used for downstream tasks, such as node classification or link prediction.
- ▶ **No use of feature vectors:** We only use the graph topology (connections between nodes) to derive the embeddings.

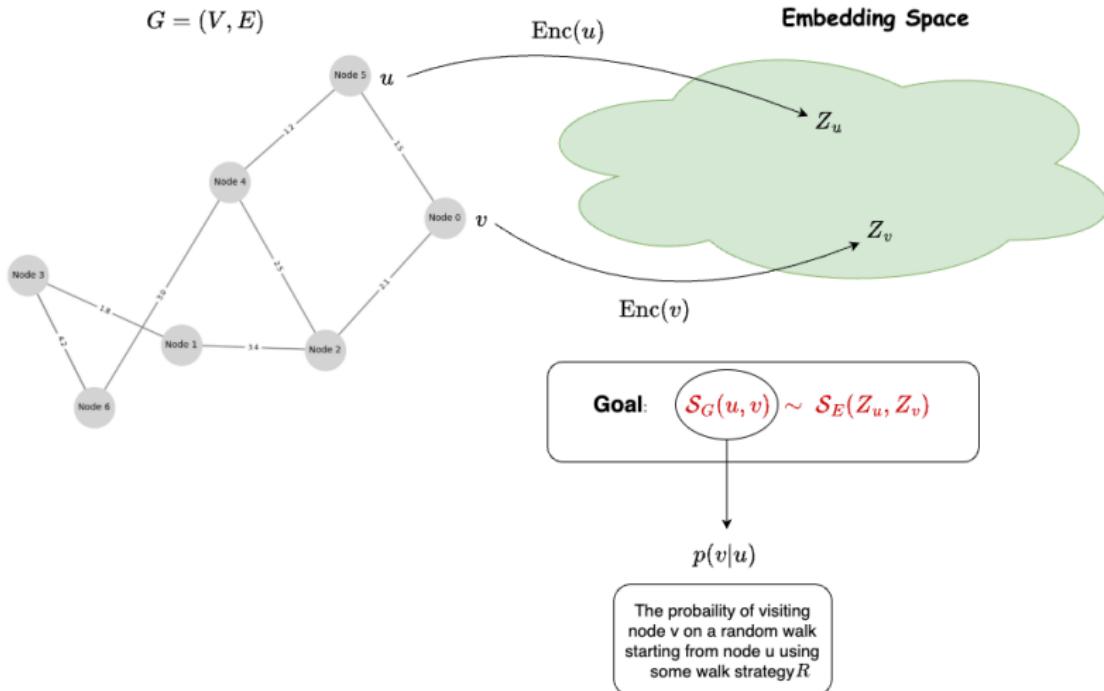

# Graph Structure-Based Embeddings: Objective

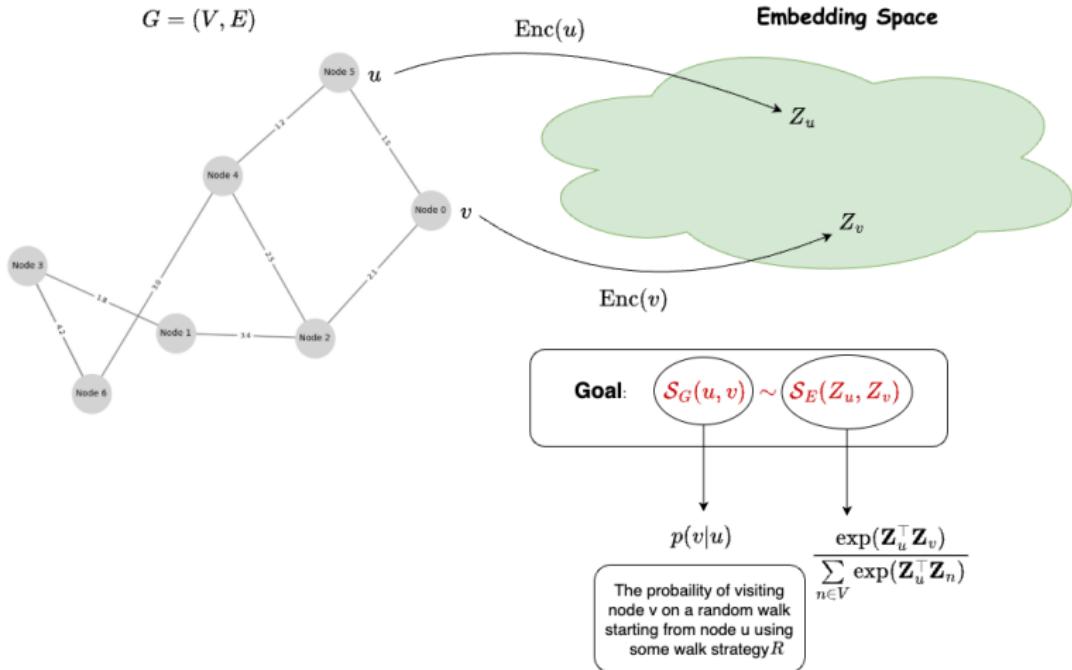

$$p(v|u)$$

The probability of visiting node  $v$  on a random walk starting from node  $u$  using some walk strategy  $R$

# Graph Structure-Based Embeddings: Objective

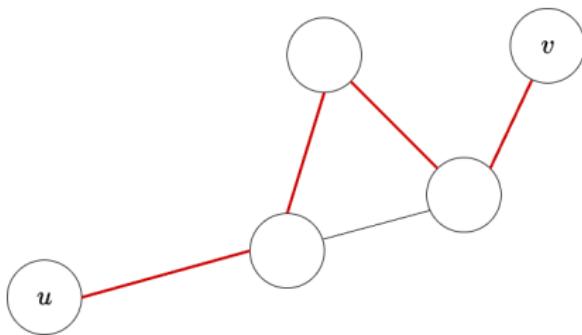

# Graph Structure-Based Embeddings: Objective

# Deep Walk algorithm

## Random Walks:

- ▶ A random walk is a sequence of steps through the graph, starting from a given node  $u$ , where each step randomly selects a neighboring node.
- ▶ The nodes visited during these walks represent the local neighborhood structure around  $u$ , denoted  $\mathcal{N}_R(u)$
- ▶ Here is an example of a random walk from node  $u$  to node  $v$ .

# Determining Neighbors Using Random Walks

---

## Algorithm Fixed-Length Random Walks

---

**Require:** Graph  $G = (V, E)$ , starting node  $u$ , walk length  $L$ , number of walks  $N$

**Ensure:**  $\mathcal{N}_R(u)$  Multiset of nodes visited during random walks starting from  $u$

```
1: Initialize an empty multiset of neighbors: neighbors  $\leftarrow []$ 
2: for  $n = 1$  to  $N$  do                                 $\triangleright$  Perform  $N$  random walks
3:     Initialize current_node  $\leftarrow u$ 
4:     for  $l = 1$  to  $L$  do                       $\triangleright$  Walk for  $L$  steps
5:         Sample a random neighbor  $v \in \text{Neighbors}(\text{current\_node})$ 
6:         neighbors.append( $v$ )
7:         current_node  $\leftarrow v$ 
8:     end for
9: end for
10: return neighbors
```

---

# Introducing Node2Vec: Biased Random Walks

- ▶ The Node2Vec algorithm modifies traditional random walks by introducing **biases** that control how the walk explores the graph.
- ▶ This bias allows us to interpolate between two extremes:
  1. **Local Behavior:** Tendency to return to previously visited nodes, capturing local neighborhood structures. This is controlled by the **return hyperparameter  $p$** .
  2. **Global Behavior:** Tendency to explore new, distant nodes, capturing the global structure of the graph. This is controlled by the **in-out hyperparameter  $q$** .
- ▶ By adjusting  $p$  and  $q$ , Node2Vec generates embeddings that can reflect different graph traversal strategies.
- ▶ This flexibility makes Node2Vec suitable for capturing diverse graph structures. (See Programming Session 6).

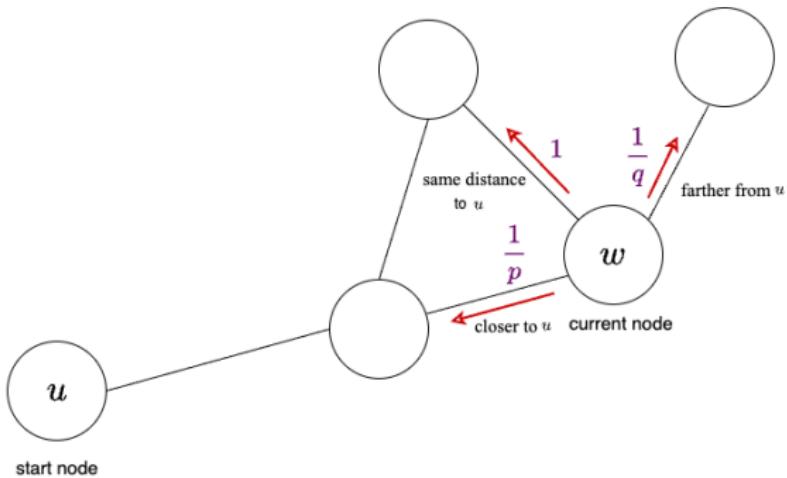

# Introducing Node2Vec: Biased Random Walks

- ▶ When the walk moves from node  $u$  to  $w$ , the neighbors of  $w$  are categorized based on their distance to  $u$ .
- ▶ We define the following **unnormalized probabilities**:
  1. Nodes closer to  $u$  than  $w$  receive an unnormalized probability of  $\frac{1}{p}$ .
  2. Nodes farther from  $u$  than  $w$  receive an unnormalized probability of  $\frac{1}{q}$ .
  3. Nodes at the same distance as  $w$  from  $u$  receive an unnormalized probability of 1.
- ▶ These unnormalized probabilities are normalized to form a valid probability distribution, which guides the biased random walk.

# Introducing Node2Vec: Biased Random Walks

Here is an example of assigning the unnormalized probabilities:

- ▶ Starting at node  $u$ , the walk reaches node  $w$ .
- ▶ The probabilities assigned to  $w$ 's neighbors depend on their distance to  $u$ , as described in the previous slide.

# Determining Neighbors Using Biased Random Walks

---

## Algorithm Biased Random Walks

---

**Require:** Graph  $G = (V, E)$ , starting node  $u$ , walk length  $L$ , number of walks  $N$ , return parameter  $p$ , in-out parameter  $q$

**Ensure:**  $\mathcal{N}_R(u)$ : Multiset of nodes visited during biased random walks starting from  $u$

```
1: Initialize an empty multiset of neighbors: neighbors ← []
2: for  $n = 1$  to  $N$  do           ▷ Perform  $N$  biased random walks
3:   Initialize current_node ←  $u$  and prev_node ← None
4:   for  $l = 1$  to  $L$  do           ▷ Walk for  $L$  steps
5:     Compute probabilities using prev_node and current_node
6:     Sample the next node  $v$  based on the these probabilities
7:     neighbors.append( $v$ )
8:     Update prev_node and current_node
9:   end for
10: end for
11: return neighbors
```

---

# Training the Embedding Vectors

## Defining the Loss Function:

- ▶ Now that we know how to define  $\mathcal{N}_R(u)$ , we can derive the loss function to train the embeddings.
- ▶ The objective is to minimize the following loss function:

$$\mathcal{L}(\theta) = - \sum_{u \in V} \sum_{v \in \mathcal{N}_R(u)} \log \left( \frac{\exp(\mathbf{Z}_u^\top \mathbf{Z}_v)}{\sum_{n \in V} \exp(\mathbf{Z}_u^\top \mathbf{Z}_n)} \right)$$

Where:

- ▶  $\mathbf{Z}_i \in \mathbb{R}^D$  is the embedding vectors for nodes  $i \in V$ .
- ▶  $\theta = \{\mathbf{Z}_i \mid i \in V\}$  represents all the embedding parameters to be learned.

Graph Terminology and Representation

Graph Representation Learning: DeepWalk and Node2Vec

Graph Neural Networks

## Node2vec recap:

- ▶ Node2Vec generates embeddings by combining graph topology and biased random walks.
- ▶ Focuses solely on the graph structure, without leveraging node-specific feature vectors.

## Paradigm Shift:

- ▶ Our new objective is to incorporate both **graph structure** and **node features** into the embeddings.
- ▶ Instead of manually defining the impact of neighbors (e.g., via  $p$  and  $q$ ), we aim for the model to **learn** the importance of different neighbors.

# Message Passing Framework

## Notations:

- ▶  $\mathbf{h}_v^{(k)}$ : Learned embedding of node  $v$  at iteration  $k$ .
- ▶  $\mathcal{N}(v)$ : Set of neighbors of node  $v$ .

At each iteration, embeddings are refined by aggregating information from the local neighborhood and updating the node's representation.

## Steps for One Iteration ( $k$ ):

1. **Aggregation:** Gather information from neighbors of node  $v$ :

$$\mathbf{a}_v^{(k)} = f_{\text{aggregate}} \left( \{\mathbf{h}_u^{(k-1)} \mid u \in \mathcal{N}(v)\} \right)$$

2. **Update:** Combine aggregated information and the previous embedding to compute the new embedding:

$$\mathbf{h}_v^{(k)} = f_{\text{update}}(\mathbf{a}_v^{(k)}, \mathbf{h}_v^{(k-1)})$$

# Message Passing Framework: The Algorithm

---

## Algorithm Message Passing Framework

---

**Require:** Graph  $G = (V, E)$ , node features  $\{\mathbf{x}_v \mid v \in V\}$ , number of iterations  $K$ ,  $f_{\text{aggregate}}$ ,  $f_{\text{update}}$

**Ensure:** Final node embeddings  $\{\mathbf{h}_v^{(K)} \mid v \in V\}$

1: Initialize embeddings:  $\mathbf{h}_v^{(0)} \leftarrow \mathbf{x}_v$  for all  $v \in V$

2: **for**  $k = 1$  to  $K$  **do**

3:     **for** each node  $v \in V$  **do**

$$\mathbf{a}_v^{(k)} \leftarrow f_{\text{aggregate}} \left( \{\mathbf{h}_u^{(k-1)} \mid u \in \mathcal{N}(v)\} \right)$$

$$\mathbf{h}_v^{(k)} \leftarrow f_{\text{update}}(\mathbf{a}_v^{(k)}, \mathbf{h}_v^{(k-1)})$$

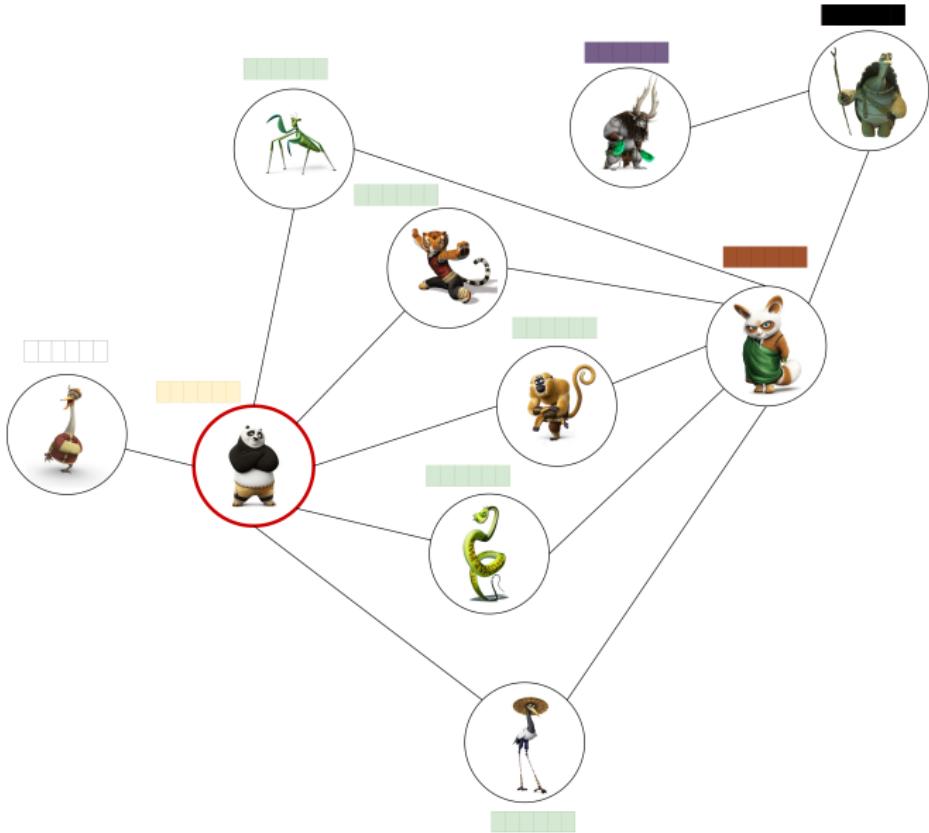

4:     **end for**

5: **end for**

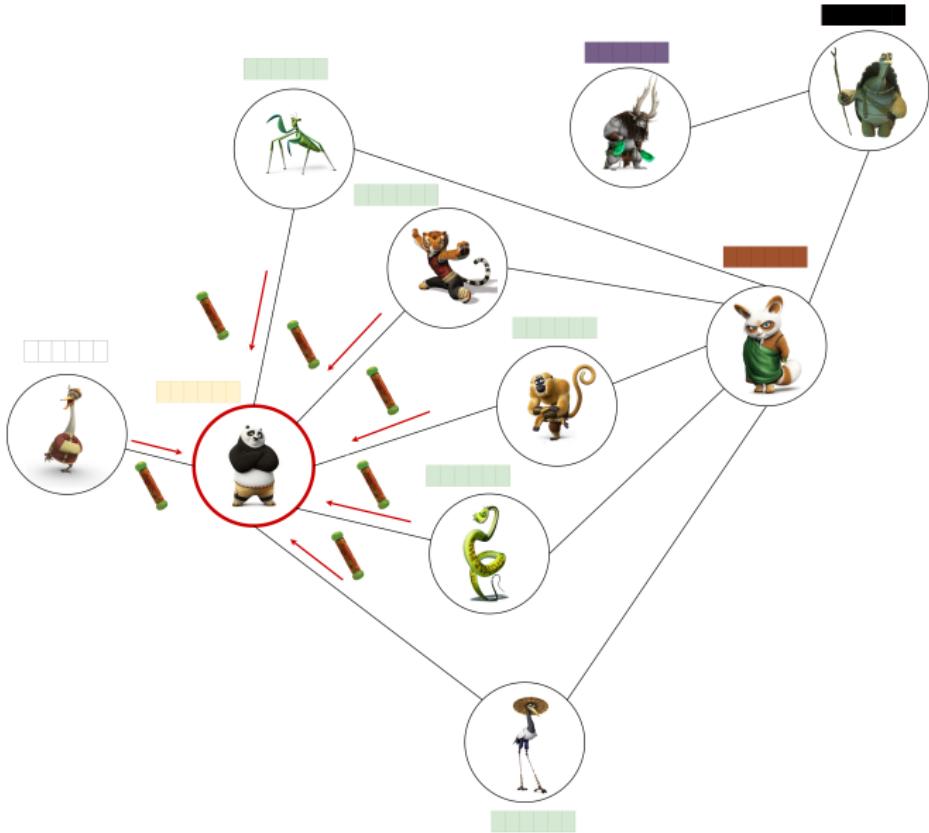

6: **return**  $\{\mathbf{h}_v^{(K)} \mid v \in V\}$

---

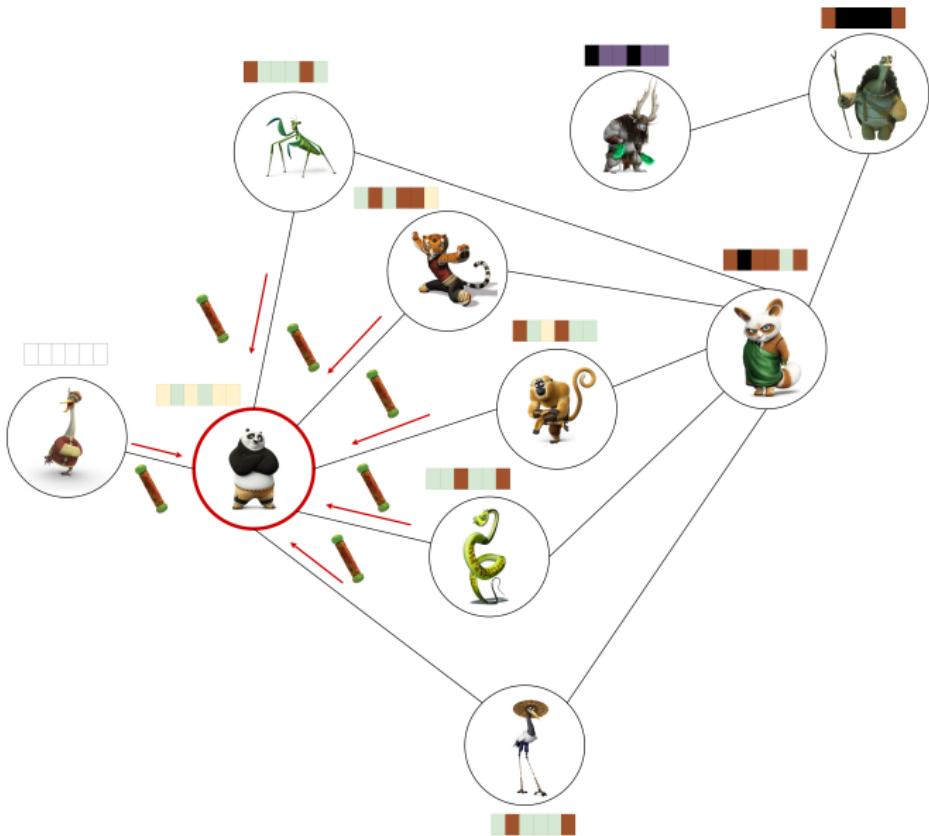

# An Example: Graph Initialization with Feature Vectors

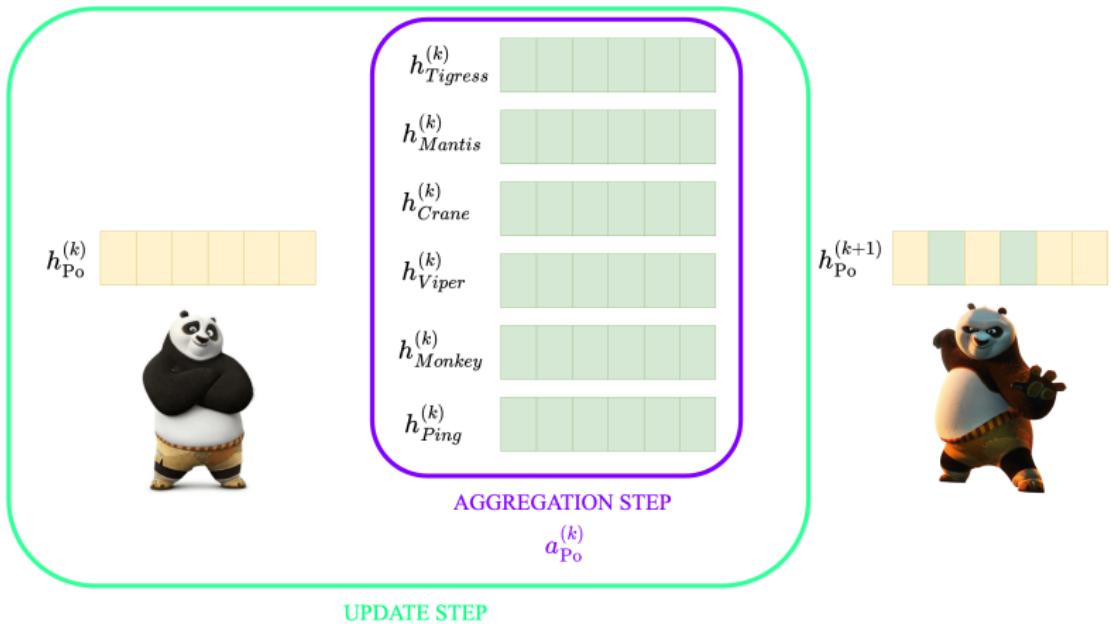

# An Example: Aggregation Step

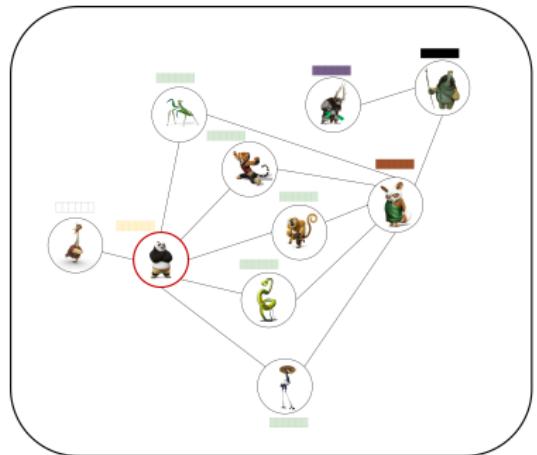

# An Example: Update Step

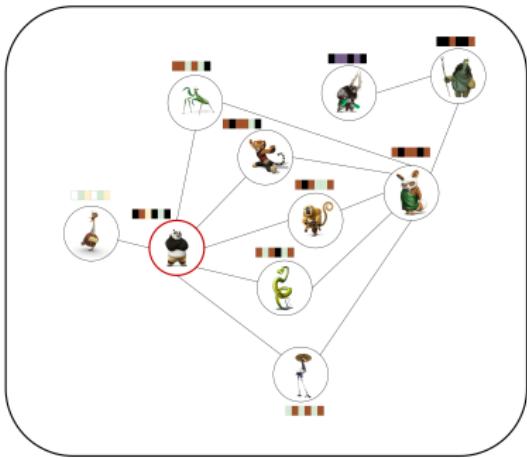

# An Example: Recap of Both Steps

# An Example: Final Embedding Vectors

...

**Aggregation Function ( $f_{\text{aggregate}}$ ):**

$$\mathbf{a}_v^{(k)} = \frac{1}{\deg(v)} \sum_{u \in \mathcal{N}(v)} \mathbf{h}_u^{(k-1)}$$

**Update Function ( $f_{\text{update}}$ ):**

$$\mathbf{h}_v^{(k)} = \sigma \left( W^{(k)} \cdot \left[ \mathbf{h}_v^{(k-1)} \parallel \mathbf{a}_v^{(k)} \right] \right)$$

**Description:**

- ▶ Aggregates the mean of the neighbors' embeddings.
- ▶ Updates the embedding with a learned linear transformation using weights  $W^{(k)}$  and a non-linear activation  $\sigma$  (e.g., ReLU).

# Graph Convolutional Networks (GCN)

**Aggregation Function ( $f_{\text{aggregate}}$ ):**

$$\mathbf{a}_v^{(k)} = \sum_{u \in \mathcal{N}(v) \cup \{v\}} \frac{\mathbf{h}_u^{(k-1)}}{\sqrt{\deg(v) \cdot \deg(u)}}$$

**Update Function ( $f_{\text{update}}$ ):**

$$\mathbf{h}_v^{(k)} = \sigma \left( W^{(k)} \cdot \mathbf{a}_v^{(k)} \right)$$

**Description:**

- ▶ **Aggregation:** Aggregates information from neighbors and the node itself, normalized by the degree of both nodes.
- ▶ **Update:** Applies a linear transformation using  $W^{(k)}$ , followed by a non-linear activation  $\sigma$  (e.g., ReLU).

# Graph Attention Networks (GAT) - Aggregation

**Aggregation Function ( $f_{\text{aggregate}}$ ):**

$$\mathbf{a}_v^{(k)} = \sum_{u \in \mathcal{N}(v) \cup \{v\}} \alpha_{vu} \mathbf{h}_u^{(k-1)}$$

**Where:**

$$\alpha_{vu} = \frac{\exp \left( \text{LeakyReLU} \left( \mathbf{a}^\top \left[ \mathbf{h}_v^{(k-1)} \| \mathbf{h}_u^{(k-1)} \right] \right) \right)}{\sum_{w \in \mathcal{N}(v) \cup \{v\}} \exp \left( \text{LeakyReLU} \left( \mathbf{a}^\top \left[ \mathbf{h}_v^{(k-1)} \| \mathbf{h}_w^{(k-1)} \right] \right) \right)}$$

**Description:**

- ▶ **Aggregation:** Computes a weighted sum of neighbor embeddings using attention coefficients  $\alpha_{vu}$ .
- ▶ **Attention Coefficients  $\alpha_{vu}$ :** Learn to assign importance to each neighbor dynamically.

# Graph Attention Networks (GAT) - Update

## Update Function ( $f_{\text{update}}$ ):

$$\mathbf{h}_v^{(k)} = \left\|_{k=1}^K \sigma \left( W_k^{(k)} \mathbf{a}_v^{(k)} \right) \right\|$$

## Description:

- ▶ **Multi-Head Attention:** Combines results from  $K$  independent attention heads by concatenation ( $\|$ ).
- ▶ **Non-Linearity:** Applies a learned linear transformation  $W_k^{(k)}$  followed by a non-linear activation  $\sigma$  (e.g., ReLU).
- ▶ GATs allow each node to focus on the most relevant neighbors dynamically, enabling better representation learning for tasks such as node classification or graph-level predictions.

# Unsupervised Training

**Objective:** Train node embeddings  $\mathbf{h}_v^{(K)}$  by leveraging the graph structure, without requiring labels.

## The Loss Function:

$$\mathcal{L}(\theta) = - \sum_{u \in V} \sum_{v \in \mathcal{N}_R(u)} \log \left( \frac{\exp(\mathbf{h}_u^{(K)\top} \mathbf{h}_v^{(K)})}{\sum_{n \in V} \exp(\mathbf{h}_u^{(K)\top} \mathbf{h}_n^{(K)})} \right)$$

Where:

- ▶  $\mathbf{h}_u^{(K)}$ : Final embedding of node  $u$  after  $K$  message-passing layers.
- ▶  $\mathcal{N}_R(u)$ : Neighborhood of  $u$  defined using some random walk strategy.
- ▶ We usually approximate the denominator using **negative sampling**.

# Supervised Training: Node Classification

**Objective:** Predict the label of each node  $v \in \mathcal{V}_{\text{train}}$  using the GNN-generated embeddings  $\mathbf{h}_v^{(K)}$ .

**The Loss Function (Cross-Entropy):**

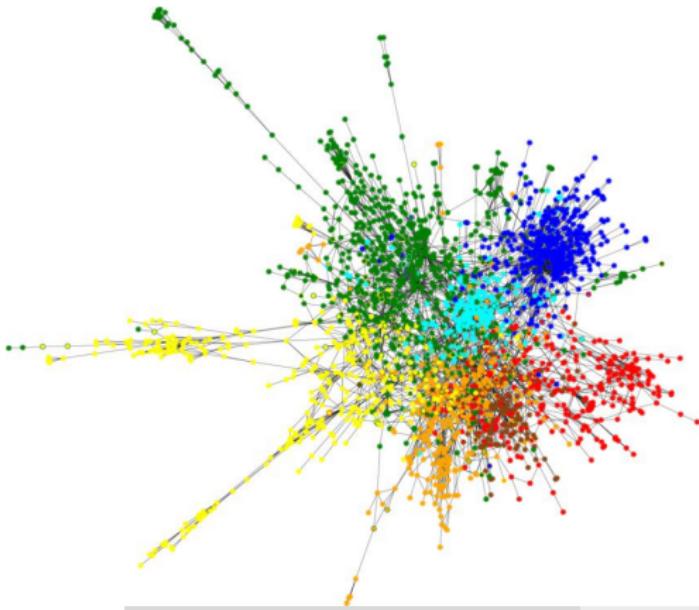

$$\mathcal{L} = - \sum_{v \in \mathcal{V}_{\text{train}}} \sum_{c=1}^C y_v^c \log \hat{y}_v^c$$

Where:

- ▶  $y_v^c$ : Ground-truth label (one-hot encoded) for node  $v$ .
- ▶  $\hat{y}_v^c = \text{softmax}\left(W_{\text{out}} \mathbf{h}_v^{(K)}\right)$ : Predicted probability of class  $c$ , computed from the node embedding.

# Programming Session: Node Classification

- ▶ During the programming session, we will work on the **Cora dataset**.
- ▶ The objective will be to build and train a **Graph Neural Network (GNN)** for node classification.

Thank you for your attention
